NEUTRON PRODUCTION CROSS SECTIONS AND ENERGIES FOR THE REACTIONS $^7\text{Li}(p,n)^7\text{Be}$ and $^7\text{Li}(p,n)^7\text{Be}^*$

HORST LISKIEN and ARNO PAULSEN

Joint Nuclear Research Center, Central Bureau for Nuclear Measurements Geel, Belgium

Center-of-mass best values for the normalized Legendre coefficients and the 0° differential cross sections as functions of input energy have been derived from various experimental results for the reactions ${}^{7}\text{Li}(p,n){}^{7}\text{Be}$ and ${}^{7}\text{Li}(p,n){}^{7}\text{Be}^{*}$ (431 keV). This information has been used to calculate laboratory differential cross sections as functions of the laboratory proton energy and neutron emission angle which are given in tabular form together with the corresponding neutron energies.

INTRODUCTION

Besides the hydrogen reactions $T(p,n)^3$ He, $D(d,n)^3$ He and $T(d,n)^4$ He the data of which have been treated recently,¹ the reaction $^7\text{Li}(p,n)^7$ Be also plays an important role as monoenergetic neutron source. The last review on this reaction was made in 1960,² when only two papers on differential data for this reaction were available. Since then the situation has been very much improved. The present evaluation takes into account all results published before December 1973.

Scope

Besides recommendations for center-of-mass (c.m.) and laboratory (lab) cross sections this review includes a tabulation of recommended neutron energies. For the calculation of these neutron energies—and other kinematic parameters needed for the transformations between the c.m. and the lab system—the most recent nuclear mass tables³ and compilation of level energies⁴ were used. The following table presents the reaction *Q*-values and thresholds.

⁷Be Excitation Reaction Energy (MeV) Q-value (MeV) Threshold (MeV) $^{7}\text{Li}(p,n)^{7}\text{Be}$ -1.6441.881 forew. 1.920 backw. $^{7}\text{Li}(p,n)^{7}\text{Be}^{*}$ 0.431 -2.0752.373 forew. 2.423 backw. $^{7}\text{Li}(p, n^{3}\text{He})^{4}\text{He}$ -3.229break-up 3.692 $^{7}\text{Li}(p,n)^{7}\text{Be}^{**}$ 4.55 -6.197.08

As may be seen from above, monoenergetic neutrons are produced only between 1.92 and 2.37 MeV proton energy. However, the second neutron group has a relatively weak intensity so that its presence can be tolerated for many experiments. Therefore this recommendation includes data for the reaction $^7\text{Li}(p,n)^7\text{Be*}$ for correction purposes, but it covers only the proton energy range up to 7 MeV, because above this energy the third neutron group complicates the situation further. This paper does not include data recommendations on the break-up reaction or on (p,n) reactions which may occur in the target support material.

Procedure

The parameterization for the first neutron group

$$\frac{d\sigma}{d\omega}(\theta) = \frac{d\sigma}{d\omega}(0^{\circ}) \sum_{i} A_{i} P_{i}(\theta). \quad \text{c.m. system}$$

is the same as adopted for the earlier work. However

for the second neutron group we chose the parameterization

$$\frac{d\sigma^*}{d\omega}(\omega) = \frac{d\sigma}{d\omega}(0^\circ)R\sum_i A_i^* P_i(\theta).$$
 c.m. system

This allows the direct use of the many results on zerodegree intensity ratios

$$R = \frac{d\sigma^*/d\omega(0^\circ)}{d\sigma/d\omega(0^\circ)}.$$
 c.m. system

If not directly quoted in the original results given by the experimenters the Legendre coefficients were determined by least-squares fits of the differential c.m. cross sections. To obtain values for A_i an A_i^* the Legendre coefficients were normalized to unity for their respective sums.

The available 0° differential cross sections were divided into three categories (a) absolute, (b) relative, and (c) relative but normalized to results of other pub-

lications. In the present work all data in category (b) and (c) were renormalized to a mean of all data in category (a). They are marked "REL" in the corresponding table and figure. Differential cross sections at 0° were corrected for the second neutron group with the c.m. ratio R if the experiment could not distinguish between the two groups.

The recommended curves for the four needed parameters $(A_i, A_i^*, R \text{ and } (d\sigma/d\omega) (0^\circ))$ were obtained by starting from smooth lines through the experimental data. This was followed by an iterative procedure of modifications to ensure the correct normalization.

$$\sum_{i} A_i = \sum_{i} A_i^* = 1$$

in the entire energy region.

The experimental neutron production cross sections (integrated over the emission angle)

$$\sigma + \sigma^* = 4\pi (d\sigma/d\omega)(0^\circ)[A_0 + RA_0^*]$$
$$\sigma^* = 4\pi (d\sigma/d\omega)(0^\circ)RA_0^*$$

are also fixed by the four compiled parameters. During the iterative procedure of modification the experimental information on these integral cross sections was taken into account and thus influenced the final recommended curves. To demonstrate the degree of consistency the compilation of 0° c.m. cross sections for the ground-state neutron group includes data which have been obtained by converting integrated neutron production cross sections. If these were relative data they were normalized to the results of Ref. 5. This operation was followed by subtraction of the recommended integrated second neutron group cross section and a division by $4\pi A_0$. It may be seen from the corresponding figure that there exists good agreement between such converted data and those directly published as 0° differential cross section. Above the ⁷Be break-up threshold the former may be too large since no correction for the break-up reaction was applied.

To obtain consistency between the experimental and recommended integrated cross sections for the second neutron group, σ^* , the recommended A_0^* -curve (and the other A_i^* -curves to satisfy the normalization condition) had to be put in the 2.5 to 3.2 MeV region at the boundaries of the available experimental results. But the experimental A_i^* results in this energy region were considered to be more uncertain than the experimental integrated cross sections of Ref. 6 which were obtained by observing the 431 keV γ -radiation (c.m. isotropic due to the $\frac{3}{2} \rightarrow \frac{1}{2}$ transition) with a Ge-Li detector and which show good consistency with the compiled parameters A_i^* , R, and $(d\sigma/d\omega)$ (0°) above 3.2 MeV.

Recommended values of differential lab cross sections, σ (θ lab) were calculated for practical use from the recommended c.m. data. Neutron energies, E_n (θ lab) are presented on the facing page. Chosen steps were 5° for the emission angle, 50 keV for the proton energy below 2.5 MeV and 100 keV above 2.5 MeV. If

laboratory data at intermediate energies are needed, interpolation of the c.m. parameters is recommended. There is a small FORTRAN program in Ref. 1 for calculation of laboratory σ 's from c.m. values. The three-dimensional plot, Fig. 3, allows a quick survey of the lab differential cross sections.

Conclusions

During the compilation of the existing experimental information it became obvious that the situation has been very much improved since the last review in $1960.^2$ However the analysis and comparison of all data still reveal the necessity of new reliable measurements for the angular distribution of the ground state neutron group below 2.2 MeV proton energy, preferably also in the double-valued region below the backward threshold. In addition there exists an inconsistency among the $^7\text{Li}(p,n)^7\text{Be*}$ data below 3.2 MeV.

In the absence of complete and comparable information on the uncertainties of the measured quantities, the mean deviation between the experimental data and the recommended curves are considered as a measure for the uncertainty of the recommended data as explained in Ref. 1. The numbers determined are given below.

It might also be worth mentioning that the present work again made it evident that valuable numerical information tends to get lost as long as there is no systematic world-wide compilation effort for charged-particle-induced reaction data similar to that which exists for neutron data.

In cases where the needed information was not published in numerical form an attempt was made to contact the authors. If this failed the numerical information had to be gained from the published figures (after magnification). The cooperation of S. A. Elbakr, K. W. Geiger, J. B. Hunt, G. Presser, D. L. Smith and L. G. Stroemberg in sending additional material after distribution of a preliminary report⁷ is gratefully acknowledged.
